(54) Title: PUMP SYSTEM WITH ERROR DETECTION FOR CLINICAL NUTRITION			
(57) Abstract			
<p>A pump for delivering a liquid from a container to a patient through a flow set. The pump includes a sensing means and a controller. The sensing means senses a parameter indicative of the pressure in the flow set. The controller has a computing and memory means for determining deviation of the parameter from a standard. Deviation is indicative of an error in the flow set. This enables supervising staff to be alerted. These errors may be incorrect assembly of the system or one of its components, inclusion in the system of an incorrect valve, impairment in the integrity of the flow set, and the existence of air bubbles in the system.</p>			

Pump System With Error Detection for Clinical Nutrition

This invention relates generally to a pump system for administering liquids to a patient; for example medicinal or nutritional solutions. The liquids may be administered enterally or parenterally. The invention also relates to a pump for use in the system and
5 to methods of administering liquids to a patient.

Systems for administering liquids to a patient are widely used in clinical settings. All of these systems comprise a container for the liquid and a flow set for delivering the liquid to the patient. In general, the liquid is either allowed to drain through the flow set to the patient under the action of gravity or is pumped through the flow set. Systems
10 using pressure sleeves on the container are also used. Systems using a pump are referred to in this specification as "pump systems".

The rate of flow of the liquid through the system is usually set to a desired rate depending on the needs of the patient. In pump systems this may be achieved by controlling the pump rate. However, particularly when intended for intravenous
15 administration of liquids, it is important to ensure that there will be no back flow of liquid in the tubing, that is away from the patient. To prevent this, a one-way valve is typically installed in the flow set. Further, because the container is typically mounted on a stand it is necessary to ensure that free-flow of liquid due to the liquid head will not occur when the pump is at rest. For this purpose, the valve, in addition to being a one-
20 way valve, also needs to prevent free flow. Therefore the valve has a certain threshold pressure which is required to open it to allow flow of liquid. The threshold pressure is also known as the "cracking point". Pump systems containing such a valve are described in PCT Application WO 95/16480 and US. Patent 5,472,420. However, incorrect valves are occasionally connected in the flow sets with serious consequences.

25 It is also important to ensure that the flow set, which is typically provided as an integral disposable set, is correctly connected to the pump to avoid pumping of liquid in a reverse direction, away from the patient. This is often left to the supervising staff and errors do occur. Also, flow sets occasionally fail and this is often not noticed until too late.

30 It is an object of the present invention to overcome or ameliorate at least one of the disadvantages of the prior art, or to provide a useful alternative.

Any discussion of the prior art throughout the specification should in no way be considered as an admission that such prior art is widely known or forms part of common general knowledge in the field.

It is an object of the present invention to overcome or ameliorate at least one of
5 the disadvantages of the prior art, or to provide a useful alternative.

Unless the context clearly requires otherwise, throughout the description and the claims, the words 'comprise', 'comprising', and the like are to be construed in an inclusive sense as opposed to an exclusive or exhaustive sense; that is to say, in the sense of "including, but not limited to".

10 Accordingly, in one aspect, this invention provides a pump for delivering

a liquid from a container to a patient through a flow set, the pump including:
a sensing means for sensing a parameter indicative of the pressure in the flow set; and
a controller having a computing and memory means for determining
5 deviation of the parameter from a standard, the deviation being indicative of an error in the flow set.

It has been surprisingly discovered that, by measuring the pressure in the flow set and comparing it to a standard, errors in the system may be detected. This enables supervising staff to be alerted. These errors may, for example, be
10 incorrect assembly of the system or one of its components, inclusion in the system of an incorrect valve, impairment in the integrity of the flow set, and the existence of air bubbles in the system.

In another aspect, this invention provides a pump system for administering a liquid from a container to a patient, the system comprising:

15 flow set comprising a tubing set connectable at one end to the container for delivery of liquid to the patient, and a one-way valve system coupled to the tubing set which permits liquid flow to the patient when a pressure differential over the valve exceeds a threshold pressure, and which prevents back flow;

a pump as defined above coupled to the tubing set.

20 Preferably, the controller causes the pump, during operation of the pump, to enter into a test phase at selected intervals, the test phase comprising a first test sequence in which the pump propels a first amount of liquid in a first direction through the flow set, and a second test sequence in which the pump propels a second amount of liquid through the flow set in a second direction, opposite the
25 first. The sensing means senses the parameter during the first test sequence and the second test sequence.

The valve system preferably comprises a valve having a liquid flow path sealed by a resilient membrane, the membrane being deformable in a desired flow direction at or above a threshold pressure for opening perforations in the
30 membrane to permit flow. Further, the valve preferably has a support preventing the membrane from deforming sufficiently in an opposite flow direction for preventing back flow.

In further aspect, this invention provides a method for administering a liquid from a container to patient using a pump system, the method comprising:

35 pumping liquid through a flow set from the container to the patient through a one-way valve system which permits flow to the patient when the

pressure differential over the valve system exceeds a threshold pressure, and which prevents back flow; and

intermittently entering a test phase comprising

pumping a first test amount of liquid in a first direction and then pumping

5 a second test amount of liquid in an opposite direction,

sampling a parameter indicative of pressure within the flow set during pumping of the first test amount of liquid and during pumping of second test amount of liquid, and

10 comparing the sampled parameters to a standard and, upon determining a difference of selected magnitude between the sampled parameters and the standard, indicating the existence of an error in the pump system.

The error which is diagnosed by the system, may, for example be:

the impairment of liquid flow through the flow set as a result of an occlusion, a rupture or a hole in the tubing, or disengagement of components of
15 the flow set, etc.;

incorrect engagement of the pump with the flow set, for example engagement in a reverse direction;

the use of incompatible components in the flow set, for example the use of an improper valve having improper flow specifications; or

20 changes in the flow parameters of the valve during operation, for example the existence of gas bubbles or gas pockets in the tubing; etc.

The present invention also provides a flow set for use in the system of the invention.

Embodiments of the invention are now described, by way of example only, with reference to the drawings in which:

Figure 1 is a schematic illustration of a pump system;

Figure 2A is a longitudinal cross-sectional view of a valve for use in the system of Figure 1 in a rest state;

30 Figure 2B is a longitudinal cross-sectional view of the valve of Figure 2A in an operational state;

Figure 3A is a graph of the flow of liquid versus time during a test phase of the pump system; and

Figure 3B is a graph of the pressure build-up versus time during a test phase of the pump system.

35 A pump system 10 is illustrated in Fig. 1. The pump system 10 comprises a pump 14 with a control unit 15, and a flow set 12. The pump 14 is preferably a

peristaltic pump but any type of pump which is able to pump liquid at controlled flow rates suitable for clinical applications may be used. The control unit 15 typically comprises a control panel 15a which has a display 15b and a key pad 15c. The key pad 15c may be used for manual control of the pump, data entry, and the like. The control unit 15 also includes a microprocessor (not shown) for controlling and activating the pump and for data storage. A memory (not shown) may be associated with, or be incorporated in, the microprocessor. If desired, the control unit 15 may also include an audio, visual or dual alarm signalling means.

The flow set 12 is made up of a tubing set 16 which is connected to a liquid container 18 at one end and a connector 20 at the other end. A drip chamber 21 and a one-way valve 22 are coupled to the tubing set 16 between its ends. In this embodiment, the drip chamber 21 is positioned beneath the liquid container 18, upstream from the pump 14. The one-way valve 22 is positioned downstream from the pump 14. As is conventional, the connector 20 may be connected to a catheter, an enteral feeding tube, etc. When not in use, the free end of the connector 20 is covered by a cover 26.

The pump 14 is coupled to the tubing set 16 and is able to pump liquid in either direction. Therefore, from the container 18 to the connector 20 (the forward direction), and towards the container 18 (the reverse direction).

The pump 14 also includes a sensing means for sensing a parameter indicative of the pressure in the flow set 12. The sensing means (not shown) is conveniently a tube diameter gauge which measures the diameter of the tubing set 16. Then, using the known resiliency of the tubing set 16, the pressure in the tubing set 16 may be determined by the microprocessor. The tube diameter may for example, be a strain gauge, an optical sensor, and the like. Alternatively, other known means of determining pressure in the tubing set 16 may be used. For example, conventional pressure gauges may be connected into the tubing set 16. The pressure parameter is preferably repeatedly sampled at short time intervals so that a curve of pressure change with time may be developed.

The one-way valve 22, shown in cross-section in Fig. 2, has a housing 30 formed of a first housing member 32 and a second housing member 34. The first housing member 32 has a recess in it into which the second housing member 34 is accommodated in a sealed manner. The second housing member 34 also has a recess in it so that a chamber 35 is defined between the first and second housing members 32, 34.

The first housing member 32 has an inlet tube 36 which is connected to

the chamber 35 by means of an entry port 37. An annular rim 38 projects into the chamber 35 from the floor of the recess of the first housing member 32, about entry port 37. The second housing member 34 has an outlet tube 39 which is connected to the chamber 35 by means of an exit port 40. Both the inlet tube 36 and the outlet tube 39 are sized to be sealingly engaged by the tubing set 16. 5 which permits liquid to flow from the chamber.

The first housing member 32 has an annular shoulder 41 projecting from the floor of its recess at the circumference of its recess. The annular shoulder 41 and the annular rim 42 of the second housing member 34, when the second 10 housing member 34 is fitted in the recess of the first housing member 32, form an annular clamp.

A resilient membrane 44 is clamped between the annular shoulder 41 and the annular rim 42 in the annular clamp. In the rest state of the valve 22 shown in Fig 2A, the membrane rests on the annular rim 38 projecting from the first 15 housing member 32. The membrane 44 is made of a resilient flexible material, typically sterilisable material such as silicon, rubber or any other suitable material. The membrane 44 has a plurality of slits 46 (two shown in this cross-sectional view) which, in the rest state shown in Fig. 2A, are closed and do not permit flow of liquid through it.

When liquid is propelled through the inlet tube 36, the membrane 44 is stretched and deflected as shown in Fig. 2B. Once a selected threshold pressure differential is reached and the membrane 44 is sufficiently stretched, the slits 46 20 widen and open to allow flow of liquid from the inlet tube 36, through the chamber 35, to the outlet tube 39. The flow is represented by the arrows in Fig. 2B. Typically, the membrane 44 is designed so that slits 46 will open only when the pressure differential over the membrane exceeds about 20 kPa. This prevents undesired free flow of the liquid from the container 18, which in a clinical setting is typically placed on a stand of a height of about 2 metres.

For flow in the reserve direction, the membrane 44 cannot deflect 30 sufficiently since it is held against the floor of the recess of the first housing member 32. Therefore the valve 22 also prevents back flow of liquid.

In use, the control unit 15 causes the pump 14 to operate in a duty cycle which has an administration phase and a test phase. The test phase is entered at selected, intermittent intervals. Typically, test phase is entered immediately after 35 the pump system 10 has been set up, prior to initiation of the first administration phase. Thereafter, the test phase is entered at selected intervals, which may be

randomly selected, between consecutive administration phases. Thus, the pump 14 may operate in a duty cycle of a first test phase, followed by an administration phase and then repeatedly through test phases and administration phases. In general, the test phases are of much shorter duration than the administration phases.

During the test phase, the integrity of the flow set 12 is checked. Also, correct assembly of the system 10 and the presence of the correct components of the flow set 12, and particularly the valve 22, are checked. Further, the existence of air pockets or bubbles in the tubing set 16 may be detected.

A test phase sequence is shown graphically in Fig. 3. As illustrated in Fig. 3A, during a first step 50 of the test phase, the pump 14 propels a small amount of liquid, for example about 0.5 ml, in a reverse direction, and then, in a second step 52, propels another small amount of liquid, for example about 0.4 ml, in a forward direction. The pressure change, relative to atmospheric, in the downstream portion of the flow set 12 (that is between the pump 14 and the valve 22) is shown in Fig. 3B.

If the pump system 10 has no faults, the pressure change is given by the solid line in Fig. 3B. In the first step 50, the pressure drops below atmospheric. In the second step 52, the pressure increases above atmospheric. The pressure is expected, in the second step 52, to increase to the cracking (threshold) pressure of the valve 22. As mentioned above, this is typically about 20 kPa. This pressure is maintained while the pump 14 is operating. When the pump 14 is then stopped, the pressure slowly declines to the zero level. This pressure curve, the no-fault curve, forms a standard which is stored in the microprocessor.

There may be several operative faults in the pump system 10. One possible fault is reverse assembly of the valve 22 in the flow set 12. Another possible fault is the reverse engagement of the pump 14 with the flow set 12 (in which case the pump 14 in a "forward" operational state in fact propels liquid in a reverse direction). Both of these faults will result in a pressure curve which is essentially a mirror image of the standard pressure curve. This faulty pressure curve is shown in Fig. 3B by the dashed line marked I. Another possible fault is leakage in the flow set 12 or the existence of air pockets or air bubbles (e.g. as foam) in the flow set 12. In this case, the pressure changes will be more moderate pressure than that of the standard curve; this is shown in Fig. 3B by the dashed-dotted lines marked II. A further possible fault state occurs when a valve 22 with an incorrect cracking pressure is used. In this case, the pressure curve

during the first step 50 will be essentially the same as the standard curve. However, during the second step 52, the pressure will reach higher or lower maximum value than the standard curve; this is represented in Fig. 3B by dotted lines III' and III'', respectively. Yet another possible fault is where the valve 22 is omitted entirely. In this case there will be substantially no pressure change and the pressure curve will essentially follow the abscissa (marked IV in Fig. 3B).

It will be appreciated that, in the test phase, the pump 14 need not first propel liquid in the reverse direction and then in the forward direction. In particular, this sequence may be reversed such that, during the test phase, the pump 14 first propels liquid in the forward direction and then in the reverse direction. This is merely a matter of appropriately setting the control unit 15. However, in this case, the standard pressure curve should be appropriate for an inverted test sequence.

During the test phase, the pressure curve which is determined is compared to the standard pressure curve stored in the memory in the control unit 15. In the event that the determined pressure curve deviates from the standard curve, the microprocessor indicates the presence of an error. It will be appreciated that the microprocessor may permit small deviations from the standard curve prior to indicating the presence of an error.

Upon the microprocessor indicating the presence of an error, the control unit 15 may, depending upon the error detected, initiate an alarm signal and prevent the pump 14 from entering into an administration phase. This may not be necessary if the error is the existence of air bubbles or air pockets. In this case, the control unit may halt the pump 14 for a short period of time, typically about 30 seconds, to allow possible air pockets to rise up in the tubing set 16 towards the container 18. Then the control unit 15 causes the pump 15 to enter into another test phase. If this fault is not detected again, the pump 14 will then be induced to enter into an administration state.

It will be appreciated that numerous modifications may be made to the preferred embodiments without departing from the scope of the invention as set out in the claims. For example, it is not essential for a drip chamber 21 to be connected in the flow set 12. Similarly, it is not essential that the flow set 12 use a one way valve 22 as described above. Other valve types and arrangements may be used; for example a combination of a one way valve and a valve which opens upon a threshold pressure being reached.

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:-

1. A pump system for delivering a liquid from a container to a patient through a flow set, the system including:

a flow set comprising a tubing set connectable at one end to the container for
5 delivery of liquid to the patient, and a one-way valve system coupled to the tubing set which permits liquid flow to the patient when a pressure differential over the valve exceeds a threshold pressure, and which prevents back flow, and

a pump having

(i) a sensing means for sensing a parameter indicative of the pressure in the
10 flow set; and

(ii) a controller having a computing and memory means for determining
deviation of the parameter from a standard, the deviation being indicative of an
error in the flow set, wherein the controller causes the pump during operation of
the pump, to enter into a test phase at selected intervals, the test phase comprising
15 a first test sequence, in which the pump propels a first amount of liquid in a first
direction through the flow set, and a second test sequence in which the pump
propels a second amount of liquid in a second direction, opposite the first through
the flow set;

the sensing means sensing the parameter during the first test sequence and the second
20 test sequence.

2. A pump system according to claim 1, in which the sensing means measures
changes in the diameter of tubing in the flow set for sensing the parameter indicative of
the pressure.

3. A pump system according to claim 2 in which the sensing means is a tube diameter
25 gauge.

4. A pump system according to claim 1 in which the valve system comprises a valve
having a liquid flow path sealed by a resilient membrane, the membrane being
deformable in a desired flow direction at or above a threshold pressure for opening
perforations in the membrane to permit flow.

5. A pump system according to claim 4, in which the valve has a support preventing
30 the membrane from deforming sufficiently in an opposite flow direction for preventing
back flow.

6. A pump system according to claim 5 in which the valve system comprises a valve having a liquid flow path sealed by a resilient membrane, the membrane being deformable in a desired flow direction at or above a threshold pressure for opening perforations in the membrane to permit flow.
- 5 7. A pump system according to claim 6 in which the valve has a support preventing the membrane from deforming sufficiently in an opposite flow direction for preventing back flow.
8. A pump substantially as herein described with reference to any one embodiment and its associated drawings.
- 10 9. A pump system substantially as herein described with reference to any one embodiment and its associated drawings.
10. A method for administering a liquid substantially as herein described with reference to any one embodiment and its associated drawings.
